# THE SYNTHESIS OF NEW COORDINATION POLYMER USING CRYSTAL 

 ENGINEERING, SELF-ASSEMBLY, AND HYDROTHERMAL SYNTHESIS byLei Fu, B.S.

THESIS
Presented to the Faculty of The University of Houston-Clear Lake In Partial Fulfillment Of the Requirements For the Degree

MASTER OF SCIENCE in Chemistry

THE SYNTHESIS OF NEW COORDINATION POLYMER USING CRYSTAL ENGINEERING, SELF-ASSEMBLY, AND HYDROTHERMAL SYNTHESIS
by
Lei Fu

APPROVED BY

Jack Y. Lu, Ph.D , Chair

Yi Su, Ph.D, Committee Member

Rio Carlo Lirag, Ph.D, Committee Member

Jack Y. Lu, Ph.D, Committee Member

RECEIVED/APPROVED BY THE COLLEGE OF SCIENCE AND ENGINEERING:

[^0]Ju H. Kim, Ph.D. Dean

## Acknowledgements

I want to thank the thesis committee for providing me the opportunity to learn. Thanks to Dr. Jack Lu for guiding me patiently during this research. Thanks to Dr. Liangzi Deng and Shuyuan Huyan for their assistance in magnetic analysis. Thanks to Dr. Weiguo Zhang for his TGA instrument assistance. Thanks to Welch Foundation for the financial support. I also want to thank my family who gave me the chance to learn and finish this thesis. Special thanks to my father Xiong Fu, without his strong support, this thesis would not be finished. Finally, thanks to all of my family member and friends who supported me for this long time.

# ABSTRACT <br> THE SYNTHESIS OF NEW COORDINATION POLYMER USING CRYTAL ENGINEERING, SELF-ASSEMBLY, AND HYDROTHEMOL SYNTHESIS 

Lei Fu<br>University of Houston-Clear Lake, 2018

Thesis Supervisor: Jack Y. Lu, Ph.D.

The emphasis of this thesis is to design and synthesize innovative coordination polymers through crystal engineering, self-assembly, and hydrothermal synthesis. The thermal and magnetic properties of the coordination polymers are analyzed.

## CHAPTER I:

## INTRODUCTION

The porous materials which consist of metal organic framework have been studied over decades. The design of coordination polymer is becoming the most challenging work. It is linking inorganic and organic chemistry. The coordination polymers can be used as molecular adsorbents, gas storage, drug-delivery agents, and sensors for the detection. ${ }^{1}$ The various applications can lead to various materials and structures. The characteristic of the polymer depends on the variety of metal center and organic ligands. The chemical bond inside the coordination polymers are usually strong and more stable. ${ }^{3}$ The coordination polymer containing two-dimensional and three dimensional open-framework coordination polymers has drawn the most interest in the recent year. ${ }^{2-5}$ Since the structure and topology lead to the important properties of polymers, the design and construction of the new porous materials with specific network become an important and topical subject. ${ }^{2-5}$ There are many factors that determine the structures of the polymer, such as coordination environment of metal, types of ligands, and noncovalent interactions. ${ }^{2-5}$ The synthetic strategies include oxidation reaction, simultaneous substitution, conventional solution methods and unexpected reduction reaction. ${ }^{2-5}$ The hydrothermal synthesis is widely used in recently years. ${ }^{6-10}$ More and more coordination polymers were synthesized through hydrothermal thesis even these last two years. ${ }^{11-15}$ The hydrothermal synthesis has been used in this thesis research. Following this thesis research, the crystal engineering, self-assembly and hydrothermal synthesis were used to design and synthesize the new coordination polymers. The successful synthesized polymer was analyzed including single crystal polymeric structural characterization, thermal stability, element consistence, and magnetic property measurements.

## CHAPTER II:

## BACKGROUND

## Structure

The structure of the inorganic crystal was first concerned by A.F. Wells. Wells has published a series of papers concerning the structure of the inorganic solids. Well has defined the crystal structure using the terms of their topology. ${ }^{17}$ Robson was the first person to use the term and expend Wells' work on the coordination polymer. ${ }^{17}$ The first generation of the coordination polymers was synthesized in 1990s. ${ }^{16}$ In mid 1990s, Dr. Zaworotko and his student Len Macgillivray studied the transition metal moieties serving as nodes then connected by organic ligands, which synthesized different structures of the coordination polymer. ${ }^{16}$ Zaworotko and his student successfully synthesized the coordination geometries of diamonded, ladder, octahedral, bilayer nets, and square grid. Then more and more coordination polymers were synthesized since 1990s.

The majority of coordination polymers usually concluded as four types of the structure. The four type of structures are zero, one, two and three dimensional structure. Zero dimensional structure is the basic structure of the coordination polymer. It is similar to the single building block of the polymer structure. The sample of this structure which is known in zeolites. The zero-dimension structure polymer can be constructed by sharing the edges of the molecular moieties and generating the one, two, three dimensional structures. The sample of one-dimensional structure can be shown in figure 1. ${ }^{17}$

## Fig. $1{ }^{17}$ Zero-dimensional structure

One-dimensional structure can usually separate into three types. They are linear, zigzag line, and ladder shape polymers. Both zigzag line and ladder shape are one dimensional structure polymer. In 2004, Hiromi Ohi and his research group had successfully synthesized the one dimensional coordination polymer complexes ( $\left[\mathrm{Cu}^{\text {II }}\right.$ $\left.\left.(\mathrm{L}) \mathrm{Cl}_{2}\right] \cdot \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)_{\mathrm{n}},\left(\left[\mathrm{Co}^{\mathrm{II}}{ }_{3}(\mathrm{~L})_{2} \mathrm{Cl}_{6}\right] \cdot 2 \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)_{\mathrm{n}}$, and $\left(\left[\mathrm{Zn}^{\mathrm{II}} 3(\mathrm{~L})_{2} \mathrm{Cl}_{6}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)_{\mathrm{n}}$ with the structure zigzag line, linear chain, and ladder shape. ${ }^{18}$ The ligand L used in this research is 1,3,5-triethylbenzene. Which is shown in figure 2.
(A)

Fig. $2^{18}$ Ligand of 1,3,5-triethylbenzene
The copper complex which contains the $\mathrm{CuCl}_{2}$ and the ligand with ratio 1:1. The $\mathrm{CuCl}_{2}$ is connected to two nitrogens of pyridine, thus constructing a zigzag chain structure polymer. ${ }^{18}$ When replacing the $\mathrm{CuCl}_{2}$ with $\mathrm{CoCl}_{2}$, the ratio of metal and ligand changes to $3: 2$, and a linear polymer can be successfully synthesized. In the cobalt complex, the $\mathrm{CoCl}_{2}$ is connected with all three nitrogen. The zinc complex uses $\mathrm{ZnCl}_{2}$ as the metal center. All three nitrogens are connected with metal, thus synthesizing the ladder shape polymer. All three types of the polymer can be shown in figure 3 .

Fig $3^{18}$ One dimensional coordination polymer

A two-dimensional coordination polymer is usually constructed from a onedimensional structure. A two-dimensional structure is similar to a sheet structure. The sample of two-dimensional coordination polymer can be copper(I) complexes which was synthesized by Hyun Jee Kim and his research group. The ligands used in this research are shown in figure $4 .{ }^{19}$

Fig $4{ }^{19}$ Ligands for two-dimensional coordination polymer

The first polymer was synthesized through reaction $\mathrm{O}_{3} \mathrm{~S}_{2}$-macrocycle $\mathrm{L}^{1}$ and CuI . The two dimensional coordination polymer $\left\{\left[\left(\mathrm{Cu}_{4} \mathrm{I}_{4}\right)\left(\mathrm{L}^{1}\right)_{2}\right] \cdot \mathrm{CH}_{2} \mathrm{Cl}_{2}\right\}_{\mathrm{n}}$ is synthesized. The layer structure was extended from $\mathrm{Cu}_{4} \mathrm{I}_{4}$ located in the center of four macrocycles. ${ }^{19}$ The second polymer was synthesized through reaction $\mathrm{O}_{3} \mathrm{~S}_{2}$-marcrocycle $\mathrm{L}^{2}$ and CuI . The one dimensional coordination polymer $\left\{\left[\left(\mathrm{Cu}_{4} \mathrm{I}_{4}\right)\left(\mathrm{L}^{2}\right)_{2}\right] \cdot 0.8 \mathrm{CH}_{2} \mathrm{Cl}_{2} \cdot 0.2 \mathrm{CH}_{3} \mathrm{CN}\right\}_{\mathrm{n}}$ was synthesized. The $\mathrm{Cu}_{4} \mathrm{I}_{4}$ in this polymer which located at the node of the tubular channel. ${ }^{19}$

Third coordination polymer is the two dimensional polymer $\left[\left(\mathrm{Cu}_{2} \mathrm{I}_{2}\right)\left(\mathrm{L}^{3}\right)_{2}\right]_{\mathrm{n}}$. The $\mathrm{Cu}_{2} \mathrm{I}_{2}$ is connected with two sulfur tetrahedrally. ${ }^{19}$ The forth complex is also a two-dimensional structure. The formula of this complex is $\left[\left(\mathrm{Cu}_{2} \mathrm{I}_{2}\right)\left(\mathrm{L}^{4}\right)_{2}\right]_{\mathrm{n}}$. For the asymmetric structure in this polymer, the unit contain two $\mathrm{L}^{4}$ ligand and one $\mathrm{Cu}_{2} \mathrm{I}_{2}$. One of the sulfur atom remains unbonded, the other two sulfurs are connected with the ligand. Three of the coordination polymer are two dimensional structure, and one of the polymers is one dimensional structure. The structure of all four polymers in these research can be shown in figure $5 .{ }^{19}$

Fig. $5^{19}$ Two-dimensional coordination polymer

When two-dimensional net structure is constructed together layer by layer, it becomes three-dimensional structure coordination polymer. The sample of a threedimensional polymer can be $\left[\mathrm{K}_{3} \mathrm{Co}_{2}\left(\mathrm{~L}^{\mathrm{C} 4}\right)_{3}(\mathrm{EtOH})_{6}\right] \mathrm{Cl}$, which was synthesized by Yu-Juan Liu and her research group. The ligand involved in this research is 25,27-bis(hydroxycarbonylmethoxy)-26,28-dimethoxyp-tert-butylcalix[4]arene $\left(\mathrm{H}_{2} \mathrm{~L}^{\mathrm{C4}}\right) .{ }^{20}$ The structure of the ligand can be shown in Fig.6. ${ }^{20}$

Fig. $6^{20}$ Ligands for three-dimensional coordination polymer

The three-dimensional polymer which was synthesized using $\mathrm{H}_{2} \mathrm{~L}^{\mathrm{C} 4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$ and $\mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$. The three-dimensional structure contain three-connecting nodes and 4-fold helices which are interconnected of the same handedness. The $\mathrm{Co}^{2+}$ is three connection ions which are linked by $\left[\mathrm{K}\left(\mathrm{L}^{\mathrm{C4}}\right)\right]^{-}$bridges. The $\mathrm{Co}^{2+}$ is six coordinate in the center of an octahedron connected by six oxygen atom. And the $\mathrm{K}^{+}$is connected to the oxygen atom of the hydroxycarbonylmethoxy groups. The completed three dimensional structure can be shown in figure $7 .{ }^{20}$

Fig. $7^{20}$ Three-dimensional coordination polymer

## Cavities

One of the most important characteristic of coordination polymer is the large size of cavities. And the function of the polymer usually depends on which material is used to synthesize the polymer and the cavity of the polymer. The research on the cavities in porous materials is becoming more important. One of the research studies discusses the coordination polymer 1,1-dicarboxylate (ccdc). The polymer is synthesized through $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and Hccdc. The coordination form in one unit can be shown in figure $8 .{ }^{21}$

Fig. $8^{21}$ Ligand of Hccdc

The crystal structure can be shown in figure $9 .{ }^{21}$

Fig. $9^{21}$ Coordination polymer cavities

The ccdc connects with two $\mathrm{Cu}^{2+}$ centers give a two dimensional sheet structure polymer. The bond angle of ccdc and $\mathrm{Cu}^{2+}$ gives the polymer small square cavities. ${ }^{21}$ The cavities have $4 \times 4 \times 6 A^{3}$ in the crystal. ${ }^{21}$ The cavities of these polymer can used to trap the methanol molecules, which is isolated from the outside. ${ }^{21}$ It is the sample of cavities affecting the structure and function of the polymer.

## Interpenetration

When two independent structures interpenetrate together, it forms an interpenetration structure. The example of the interpenetration polymer was synthesized by Matthew A. Withersby and his research group. The three dimensional polymer $\left[\mathrm{Cd}_{2}(4,4-\text { pytz })_{3}\left(\mu-\mathrm{NO}_{3}\right)\left(\mathrm{NO}_{3}\right)_{3}(\mathrm{MeOH})\right]$ is an example of has interpenetration structure. The coordination polymer structure can be shown in figure $10 .{ }^{22}$

Fig. $10^{22}$ Coordination polymer with interpenetration structure

In this polymer, the Cd center provides T -shaped connecting units. The units constructed ladder shape polymer. The independent ladder is interpenetrated perpendicularly by other two independent ladders. The ladder that was interpenetrated by each other extended and formed three dimensional coordination polymer which contains an interpenetration structure. This phenomenon would also affect the cavity network.

## Crystal Engineering

Crystal engineering is the process of designing and performing the crystal structure synthesis. By selecting the metal and the ligand, the structure of the coordination polymer can be predicted before performing the actual synthetization process. Metal is a very important part in coordination polymer. The metal ion usually become the connection node in the polymer. Based on the oxidation state, the geometry of the connection can be determined. The ligand of the polymer usually becomes the framework of the polymer. One of the examples can be the one dimensional coordination
polymers $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(4,4\right.$-bipy) $\mathrm{SO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (figure 11) and $\mathrm{Co}(\mathrm{DMSO})_{2}\left(4,4\right.$-bipy) $\mathrm{Cl}_{2}$ (figure 12). ${ }^{23}$

Fig. $11^{23} \mathrm{Co}(\mathrm{H} 2 \mathrm{O})_{3}(4,4$-bipy $) \mathrm{SO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$

Fig. $12^{23} \mathrm{Co}(\text { DMSO })_{2}(4,4$-bipy $) \mathrm{Cl}_{2}$

It is easy to distinguish that Co usually constructs the octahedral structure. In both polymers, the ligand 4,4-bipy is connected to the Co center. The connection with Co center is an octahedral structure. The ligand is the base line of the framework in the structure. The N atom connect to the Co ion and extend to the whole structure becoming the one-dimensional polymer.

By selecting metal center and organic ligand, the structure of the new coordination polymer can be preselected. It is very important to consider both metal and ligand geometry before synthesizing new coordination polymer. Through crystal engineering, there were many different coordination polymers that were synthesized during these years.

## Self-assembly

In coordination chemistry, self-assembly is different from other synthesis techniques. For example, organic synthesis usually involved multiple steps in the synthesize process. But in the coordination chemistry, all the starting material will be placed in one reaction vessel. With a thermodynamic drive, the polymers will assemble by themselves. The self-assembly process is only a one step reaction. The thermodynamic
drive makes the coordination polymer more thermodynamically stable. The polymers are more stable at room temperature. With higher thermodynamically drive, some polymers can be more stable at higher temperatures. Base on its simple process, self-assembly has become the most popular technique in coordination chemistry. ${ }^{17}$

## Hydrothermal Synthesis

In 1862, St. Claire Deville had claimed to make a name zeolite in the laboratory. ${ }^{24}$ Later in 1940s, Richard Barrer started his research and successfully reached mineral phases through hydrothermal technique. The strong salts solution was placed with high temperature $\left(170-270^{\circ} \mathrm{C}\right) .{ }^{24}$ In 1948, Barrer synthesized the first zeolite unknown as a natural mineral. ${ }^{24}$ In the current coordination chemistry, the hydrothermal synthesis usually base on the Teflon container with water or other organic solvent. Akporiaye and co-workers were the first to report the use of Teflon containers relate to hydrothermal synthesis of zeolite. ${ }^{24}$ In this research, Akporiaye had used a $10 \times 10$ chamber and varied cation systems at $100^{\circ} \mathrm{C} .{ }^{24}$ The hydrothermal synthesis in modern coordination chemistry is the Teflon container placed in a metal bomb. The bomb was then sealed and put into oven at certain temperatures for more than three days. During the time when the metal bomb in the oven, the pressure inside the Teflon container is increasing. The properties of the solvent inside the bomb such as viscosity, and density, become different. The properties of the starting material also changed, such as the metal ion, which might reduce from higher oxidation state to lower oxidation state. The sealed system with high temperature and pressure will trigger the reaction which will not happen in the room temperature. It allows the coordination polymer to grow by itself inside the bomb. Based on these characteristics of the Teflon bomb used in hydrothermal synthesis, more and more different structure of the coordination polymers were synthesized.

## Thermal Properties

The coordination polymers are widely used in different area. Some of the coordination polymers require high temperature resistance. In order to test the thermal properties, the instrument Diamond thermogravimetric/ differential thermal analyzer (DT/TGA), is used. The DT/TGA instrument contains three components, the furnace part, scale part and computer part. The furnace part allows the TGA instrument to heat the sample to a certain temperature. At the same time, the furnace is used to provide the noble gas to prevent the sample from reacting with air and forming impurities. Second part is the scale part, with a balance inside the scale part. It provides two balance beams which extend into the furnace. The balance is used to monitor the weight changes during the temperate changes. One of the balance beam is used to place the sample. Another beam is used to place the empty sample containers. By comparing the differences of two balance beams, the changes of the sample weight can be determined. Last part is the computer part, the computer is connected to the deflection sensor. The software installed in the computer is used to control and receive the data from the DT/TGA instrument. By using this work station, the testing result can be obtained. ${ }^{25}$ The example of using DT/TGA instrument can be [ Fe (ox)(bpy)] which was synthesized by Jack Y. Lu. ${ }^{26}$ This polymer is synthesized using hydrothermal technique. The starting materials were placed in the Teflon bomb. Under the high temperature condition, the polymer grows inside the bomb. The typical TGA graph for this polymer is shown in figure $13 .{ }^{26}$

Fig. $13^{26}$ TGA for [Fe(ox)(bpy)]

In figure 13, it is the polymer analyzed using TGA instrument. It contains the temperature range from 50 to $500^{\circ} \mathrm{C}$. In this graph, the solid line indicate that there is a large weight loss from 350 to $450^{\circ} \mathrm{C}$. Figure 13 shows this polymer loss about $45 \%$ of its weight, which means this polymer is thermal stable until $350^{\circ} \mathrm{C} .{ }^{26}$ The dashed line is the negative of the first derivative. This polymer undergo one step decomposition process.

Coordination polymers might have more than one step decomposition process. In this case, another type of TGA graph is shown in figure $14 .{ }^{27}$

Fig. $14^{27}$ TGA for [FeCl2(bpy)]

Figure 14 is the TGA graph for the coordination polymer $\left[\mathrm{FeCl}_{2}(\mathrm{bpy})\right]$. Three weight loss curves can be seen in this figure. ${ }^{27}$ The first derivative line has three peaks which indicate the three-step weight loss process. The reason of obtaining three step weight loss is because the functional group decomposes in different temperature. By calculating the percentage of weight loss, it can be known which functional group decomposed first and which functional group is second. For example, $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ has molecular weight $250 \mathrm{~g} / \mathrm{mol}$. If the decomposition graph gives $36 \%$ weight loss, indicates the $5 \mathrm{H}_{2} \mathrm{O}$ loss from the molecule. The peak of the first derivative is related to the functional group which the polymer obtains.

## Magnetic Properties

The magnetic moment of each sample was measured at temperatures from 2 K to 375 K and under external magnetic fields from 0 to 7 T by a Quantum Design Magnetic Properties Measurement System (MPMS).

The MPMS is an automated system that contains a temperature control system, a sample transport system, a Superconducting Quantum Interference Device (SQUID)
amplifier system and a measurement device which consists of several superconducting components:
a superconducting magnet to generate strong magnetic fields with maximum 7 T a superconducting detection coil which couples inductively
a SQUID connected to the detection coil
a superconducting magnetic shield surrounding the SQUID
A sample is moved through a second-derivative gradiometer A magnetic moment is induced in the sample by the external field H created by the superconducting magnet. As the sample is moved through the coiled wire, the magnetic flux $\Phi$ through the coils due to the sample's magnetic moment changes. An electric field E and a current in the coils are created in accordance with Faraday's Law of Induction

$$
\oint \vec{E} \cdot d \vec{s}=-\frac{d \Phi}{d t}
$$

Where ds ${ }$ is an infinitesimal displacement along the boundaries of the line integral and dt is the infinitesimal time. The induced current is inductively coupled to the SQUID detector, which acts as an exceptionally sensitive current to voltage converter due to a quantum tunneling effect. The voltage is proportional to the magnetic moment of the sample, and this value is processed and recorded by a computer.

The sample is mounted in a sample holder that is attached to the end of a tough sample rod. The sample rod enters the sample space through a special type of double seal (called a lip seal) designed to allow the rod to be actuated by a drive mechanism located outside of the chamber. The component containing the lip seals is damped onto the top of the airlock with standard O-ring seals, forming the top of the sample space.

The top of the sample transport rod is attached to a stepper-motor-controlled platform which is used to drive the sample through the detection coil in a series of
discrete steps. It is possible to use discrete steps because the detection coil, SQUID input coil, and connecting wires form a complete superconducting loop. A change in the sample's position causes a change in the flux within the detection coil, thereby changing the current in the superconducting circuit. Since the loop is entirely superconducting, the current does not decay as it would in a normal conductor. During the measurement the sample is stopped at a number of positions over the specified scan length, and at each stop, several readings of the SQUID voltage are collected and averaged. The complete scans can be repeated a number of times and the signals are averaged to improve the signal-to-noise ratio.

The currents induced in the detection coil are ideally those associated with the movement of a point-source magnetic dipole through a second-order gradiometer detection coil. To get the samples being uniformly magnetized, it requires that the sample is much smaller than the detection coil. In addition to this, the shape of a sample can also require special consideration. If a sample is very long, extending well beyond the coil during a scan, its motion in the gradiometer will not be observable, since there would be no net change of the flux in the detection coil. This is the reason that a long uniform tube can be used as a sample holder since the detection coil will get little net change of flux from the contribution of the holder. In contrast to this, when the sample is short, the current in the detection coil changes with sample position. This is because different amounts of flux exist in each loop of the detection coil. So, it is important to realize that there is a limit on the length of a sample for which accurate measurements can be made.

Our samples were carefully placed into gel caps. The gel cap was then tightly attached in the straw that connected to the sample rod. The rod was then lowered into the bore of the SQUID magnetometer. The sample was cooled to 2 K without any external magnetic field, i.e. zero-field-cooled (ZFC). At 2 K , the magnetic fields of 10 Oe and

1000 Oe were applied, respectively. Magnetic moments were measured from 2 K to 350 K , and then from 350 K to 2 K (FC). M-H loops were also measured at certain fixed temperatures between -7 T and 7 T .

## CHAPTER III

## EXPERIMENTAL

## General Techniques

In the coordination polymer synthesis, three techniques were used during these years, crystal engineering, self-assembly, and hydrothermal synthesis. Since the metal and the organic ligand determine the structure of the final product, choosing a metal is the first step of crystal engineering. The metal used in coordination polymer are usually first and second row of transition metals. The transition metal can have different oxidation states which is very important for structure design. In order to synthesize the polymer with coordination structure, the structure of the organic ligand also need to be considered. Some of the coordination polymer consists of single metal and single ligand, and some of the coordination polymer have multiple metal and multiple ligands. The weight of the starting material is decided according to the ratio of metal to ligand. Since the reaction is performed in Teflon bomb, the bomb has limited volume, the weight of each starting materials usually not over 0.24 g . According to the molecular weight, the amount of the starting material generally selected is 0.001 moles. Base on the ratio and the limitation, the moles of the material can change to 0.0005 moles or 0.0015 moles. In coordination polymer synthesis, water and polar organic solvent generally are selected as solvents. Since the volume of Teflon bomb is very small, the volume of solvent is about 6 milliliters. All the materials were placed in the Teflon bomb, then the bomb was sealed and placed in the oven. By using oven, the bomb can be heated at constant temperature for certain length of time. The time spent in the reaction is generally more than three days. With the specific temperature and time, the reaction proceeded. The length of time and the temperature differences also determined the results of the reaction. After the
reaction time, the bomb was cooled to room temperature naturally. The products were washed by water and acetone. The products were placed under a microscope after dried in the air. Viewed under the microscope, crystals had formed or not can be determined.

## Starting Materials

The starting materials used in this thesis research were purchased from Sigma Aldrich. The purity of the chemicals was highest purity. The di-water was used as solvent and to wash the products.

## Equipment

When the crystals were found under the microscope, they need to be picked up without any impurities attached together. The pure crystals then were sent to the x-ray crystallographer. A $1 \mathrm{~K} C C D$ area detector equipped in the x-ray diffractometer. The data collection completed on a Siemens SMART platform diffractometer.

After the crystal structures were solved and refined well, the coordination polymers were sent to Galbraith laboratories for the elemental analysis. The content of the metal, carbon, hydrogen, and nitrogen were analyzed. The percentage of each element will be reported.

The polymer then was sent to University of Houston to test thermal properties. The equipment used for TGA analysis is DT/TGA 6300. The temperature range was set from 0 to $600^{\circ} \mathrm{C}$. And the temperature increasing rate was set at $10^{\circ} \mathrm{C}$ per minute. The gas flow used was nitrogen gas.

The polymers were then analyzed with IR spectrometer. The IR instrument used is frontier FT-IR spectrometer which was provided by the PerkinElmer Company.

The magnetic moment of each sample was measured under temperatures ranging from 2 K to 375 K and under external magnetic fields ranging from 0 to 7 T by a Quantum Design MPMS (Magnetic Properties Measurement System) SQUID (Superconducting Quantum Interference Device) magnetometer.

## CHAPTER IV

## RESULTS AND DISCUSSION

During this thesis research, 235 reactions were performed. Most of the reactions were repeated with different conditions. For instance, after selecting the metal and ligand, the reactions were performed with changing temperatures, mole ratio, lengths of time, and solvent. A table which listed all the reactions is included in this chapter. In these 235 reactions, most of the reactions failed to produce crystals. Some of the reactions form the crystals, but the crystals were either bad quality to analyze or identified as normal crystals instead of coordination polymers. Some of the crystals were reported by other research groups. Only two crystals were found in this thesis research. These two crystals have the same chemical formula but different structure. The chemical formula of the new coordination polymer is $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$. This new coordination polymer then was then analyzed IR, DT/TGA, magnetic properties, and elemental analysis. All the results are shown in this chapter.

## Reactions

## $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$

Fig. 15 Sample of complex 1

Figure 15 presents the first structure of the coordination polymer $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$. It is named as complex 1 . Complex 1 is the black crystals which synthesized by reacting $\mathrm{FeCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, 5-bromonicotinic acid (HBNA), and 4,4-bipyridine with the mole ratio 1:2:1. The materials were placed in the Teflon bomb. 6 ml of water was used as solvent. Then the bomb was put into the oven for three days. The temperature of the oven was set at $140^{\circ} \mathrm{C}$. After the reaction time finished, it is allowed to cool down to room temperature naturally. The product then was washed by di water and acetone. The product is black
crystals, and the white product was the impurities (Figure 15). The x-ray crystallography shows this coordination polymer is the two dimensional coordination polymer. It constructed the 2D layer structure. The monoclinic crystal has formula weight of 1389.57. The details of this structure are listed in Table 1.

Table 1.crystal data for complex 1

| Empirical formula $^{\mathrm{a}}$ | $\mathrm{C}_{36} \mathrm{H}_{18} \mathrm{Br}_{6} \mathrm{Fe}_{3} \mathrm{~N}_{6} \mathrm{O}_{13}$ |

| $a(\AA)$ | $11.2904(6)$ |
| $b(\AA)$ | $18.4960(11)$ |
| $c(\AA)$ | $21.4349(12)$ |
| $\beta$ ( $\left.^{\circ}\right)$ | $91.029(1)$ |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Goodness-of-fit on $\mathrm{F}^{\prime} 2$ | 1.028 |
| Final R indices $[I>4$ sigma(I) $]$ | $\mathrm{R} 1=0.0156$, wR2 $=0.0405$ |
| ${ }^{\mathrm{a}} R_{1}=\Sigma \\| F_{0}\left\|-\left\|F_{c}\right\|\right\| / \Sigma\left\|F_{0}\right\|, w R_{2}=\left[\Sigma\left(F_{0^{2}}-F_{c^{2}}\right) / \Sigma w\left(F_{0}\right)^{2}\right]^{1 / 2}$. |  |

The structure of complex 1 consists of three Fe ions. The Fe irons are sixcoordinated in the octahedral coordination sphere. The equatorial plane is Fe iron connected with four oxygen atoms from different BNA ligands. One nitrogen atom from BNA and one oxygen atom occupy in the axial position. Three Fe irons have range of $3.245 \AA-3.343 \AA$ with no bonds connected to each other. The bond length of $\mathrm{Fe}-\mathrm{N}$ is in the range of $2.202 \AA-2.225 \AA$. The bond length of $\mathrm{Fe}-\mathrm{O}$ is in the range of $1.833 \AA-2.164 \AA$. The unit cluster of this coordination polymer is shown in figure 16.

Fig. 16 Unit cluster of complex 1

Figure 16 shows the unit cluster of the polymer which indicate the coordination environment of Fe ions in complex 1. Figure 17 shows the coordination modes of BNA ligands in the polymer. The white ball indicate the carbon atom and the green ball indicate the Br atom.

Fig. 17 Coordination environment of complex 1

The nitrogen atom which shown in Figure 17 is the nitrogen in the BNA ligand. Each of the nitrogen atoms is connected to an Fe atom. And the oxygen atom is also connect to the Fe atom. The labeled Fe 3 on the left is the same atom Fe 3 on the right. So the coordination modes of the BNA ligand is $\mathrm{O} 7-\mathrm{Fe} 3-\mathrm{N} 1$ and $\mathrm{O} 8-\mathrm{Fe} 1-\mathrm{O} 1$. The atom N 4 and Fe 2 is connect to other Fe and extend to 1D and 2D structure.

Fig. 18 One dimensional structure of complex 1

Figure 18 shows the one dimensional structure of complex 1. The coordination mode is the same as shown before. When the nitrogen and oxygen are linked with different Fe ion, the 1D structure in the ab plane was formed.

Fig. 19 Two-dimensional structure of complex 1

When all the nitrogen and oxygen are connected with different Fe atom, it can extend to a two-dimensional sheet structure. The polymer structure is shown in Figure 19. The two dimensional structure is in the bc plane of the coordinate. The cycle part in Figure 19 is the one-dimensional structure fragment which shown in Figure 18. The selected bond length and angles of complex 1 is shown in Table 2.

Symmetry transformations used to generate equivalent atoms: \#1 $-\mathrm{x}+1$, $-\mathrm{y}+1,-\mathrm{z}+1 ; \# 2-\mathrm{x}+1, \mathrm{y}+1 / 2,-\mathrm{z}+3 / 2 ; \# 3-\mathrm{x}+1, \mathrm{y}-1 / 2$, $-z+3 / 2$.

Fig. 20 Sample of complex 2

Figure 20 shows the coordination polymer with same chemical formula $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ but different structure. It is named as complex 2. Complex 2 is the black crystals which is synthesized by reacting $\mathrm{FeCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, 5$-bromonicotinic acid (HBNA), and 4,4-bipyridine with the mole ratio 1:1:1. The materials were placed in the Teflon bomb. 6 ml of water was used as solvent. Then the bomb was put into the oven for seven days. The temperature of the oven was set at $140^{\circ} \mathrm{C}$. After seven days, the bomb was taken out of the oven and allowed to cool down to room temperature naturally. Then the
product is washed by di water and acetone. The product is black crystals, others are the impurities. The x-ray crystallography shows that this coordination polymer is the three dimensional coordination polymer. It constructed the three dimensional cube structure. The monoclinic crystal also has formula weight of 1389.57. The details of this structure are listed in Table 3.

The complete crystallography tables and other data for this compound is located in Appendix B.

## Table 3. Crystal data and structure refinement for complex 2.

| Empirical formula | $\mathrm{C}_{36} \mathrm{H}_{18} \mathrm{Br}_{6} \mathrm{Fe}_{3} \mathrm{~N}_{6} \mathrm{O}_{13}$ |
| :--- | :--- |
| Crystal system, space group | Cubic, $\mathrm{Pa}-3$ |
| a (A) | $20.3708(6)$ |
| $\mathrm{b}(\AA \mathrm{A})$ | $20.3708(6)$ |
| $\mathrm{c}(\AA \AA)$ | $20.3708(6)$ |
| $\alpha\left({ }^{\circ}\right)$ | 90 |
| $\beta\left({ }^{( }\right)$ | 90 |
| $\gamma\left({ }^{\circ}\right)$ | 90 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{\wedge} 2$ |
| Goodness-of-fit on $\mathrm{F}^{\wedge} 2$ | 1.058 |
| Final R indices $[\mathrm{I}>4 \operatorname{sigma}(\mathrm{I})]$ | $\mathrm{R} 1=0.0178, \mathrm{wR} 2=0.0449$ |

The structure of complex 2 unit cell also consists of three Fe ions. The Fe irons are six-coordinated in the octahedral coordination sphere. The equatorial plane is Fe iron connected with four oxygen atoms from different BNA ligands. One nitrogen atom from BNA and one oxygen atom occupy in the axial position. Three Fe irons connect to each other. The bond length of $\mathrm{Fe}-\mathrm{N}$ is in the range of $2.229 \AA$. The bond length of $\mathrm{Fe}-\mathrm{O}$ is in the range of $1.896 \AA-2.109 \AA$. The 4,4-bipyridine is not presented in the structure. The asymmetric unit showing atom numbering is shown in Figure 21.

Fig. 21 Coordination pattern for each atoms in complex 2

Figure 21 shows the coordination pattern for each atoms in the coordination polymer. It is the asymmetric unit. The oxygen and nitrogen atoms are coming from the BNA ligand. The small green ball is the Br atom from the BNA ligand.

Fig. 22 Complete coordination of Fe

Figure 22 shows the complete coordination about Fe. From Figure 22, it is shown that the Fe atom is six coordinated and octahedral structures. Four oxygen at equatorial position connected to the Fe . The oxygen atoms are coming from different BNA ligands. One of the axial position connected to nitrogen atom on the BNA ring.

Fig. 23 Complete coordination of central oxide

Figure 23 shows the complete coordination about central oxide. The Br atom is omitted. This is the unit cluster for complex 2. In this structure, each of the Fe atoms was connected to a BNA ligand through Fe-O bond. So the nitrogen of the ligand can connect to another Fe atom on the axial position.

Fig. 24 One-dimensional fragment of complex 2

Figure 24 shows the one-dimensional fragment of complex 2 in the bc plane of coordinate. It is similar to complex 1, but the connection pattern is different. And the bond length is different. In complex 2, the ligand is connected to the Fe in different angle. The ring of the BNA ligand can rotate in different direction when forming the $\mathrm{Fe}-\mathrm{N}$ bond. When the BNA ligand with different direction connect to Fe atom, it is extender to three dimensional structure.

Fig. 25 Three-dimensional packing arrangement of complex 2

Figure 25 is the partial section of the three dimensional packing arrangement of the complex 2 . Figure 25 shows the complete fragment of the complex 2 . The ring of the BNA ligand is facing different direction, so when the $\mathrm{N}-\mathrm{Fe}-\mathrm{O}$ connected, the whole structure can extend to three-dimensional structure.

Fig. 26 Complete structure of three-dimensional structure of complex 2

Figure 26 is the complete structure of the three dimensional coordination polymer.
The chemical formula is $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$. This three dimensional coordination polymer turn out to be a black cubic crystal when observing under the microscope. The selected bond length and bond angle is shown in table 4.

## FT-IR analysis

The results of the FT-IR analysis is shown in figure 27. It is corresponding to the complex 2. The peak at $1371 \mathrm{~cm}^{-1}$ corresponding to the $\mathrm{C}-\mathrm{O}$ stretching. The peaks at $1551 \mathrm{~cm}^{-1}$ and $1610 \mathrm{~cm}^{-1}$ corresponding to the C-C stretching which is the carbon located on the BNA ring. The peak at $1287 \mathrm{~cm}^{-1}$ corresponding to the $\mathrm{C}-\mathrm{N}$ stretching which is the $\mathrm{C}-\mathrm{N}$ bond on the BNA ligand.

Fig. 27 IR for complex 2

IR results indicate that the coordination polymer has successful synthesized.

## Elemental Analysis

The results of elemental analysis shown in table 5 . The calculated values will be used to compare the results. Comparing the theoretical calculations to the actual result analyzed from Galbraith Laboratories, there is only small differences. That might be due to some end groups not account for in the theoretical calculations.

## Table 5. Elemental Analyses for complex 2.

| Element | Found | Calculated |
| :--- | :--- | :--- |
| Carbon | $30.7 \%$ | $31.0 \%$ |
| Iron | $12.0 \%$ | $12.0 \%$ |
| Hydrogen | $0.88 \%$ | $1.2 \%$ |
| Nitrogen | $5.8 \%$ | $6.0 \%$ |

The elemental analysis result shows that the composition of the complex 2 is same as the chemical formula shows.

## Thermal Analysis

The result of thermal analysis for complex 2 is shown in figure 28. It is found that the complex 2 has one-step degradation process. Because there only one large jump from the TGA graph. The blue line which is the TG line. The TG line indicate the polymer started to decompose when temperature reach about $375^{\circ} \mathrm{C}$. And finish decomposing about $550^{\circ} \mathrm{C}$. I means this polymer is stable up to $375^{\circ} \mathrm{C}$. During the decomposing process, $41.8 \%$ of weight was lost. And the weight remain unchanged when the temperature cools down to room temperature. The green line which is the DTA line.

There is a peak upwards in the DTA line. It indicate that the polymer is absorbing heat during the decomposing process.

## Magnetic Analysis

Transition elements such as $\mathrm{Fe}, \mathrm{Co}$ and Ni always introduce interesting magnetic properties in the sample due to its unpaired electrons in (n-1) d orbital. Most of transition metals themselves show paramagnetic behaviors. Structural factors leading to hybridization of orbital will change the magnetic properties and electronic structure when
the transition metals are in the form of complex ions. In this scenario, $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ is interesting from both in the magnetic property and electronic structure point of view. To explore the function of the iron ions in $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$, the magnetic properties of $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ was studied in the temperature from 2 K to 375 K and under the external magnetic field from -7 T to 7 T .

Under low magnetic field ( 10 Oe ), as shown by Fig.29, the sample behaves as a typical paramagnet without any magnetic anomaly. However, a weak split for ZFC and FC curve started from 300 K was observed, so we doubted if there is any magnetic transition over 300K that leads to the split. Figure. 30 showed the magnetic measurement under an external magnetic field of 0.1 T . The green dotted line is the fit to the CurieWeiss law, the susceptibility starts to deviate from the Curie-Weiss law below $\sim 120 \mathrm{~K}$, indicating a possible enhancement of short-range magnetic correlation which have a higher Curie constant C . We suggest that it could be due to the enhancement of shortrange ferromagnetic state. ${ }^{28-32}$ Here we think the dielectric constant measurement is also
worth doing, due to the curiosity that if there will be a ferroelectric transition at 120 K .

Fig. 29 Temperature dependence of magnetic moment of $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ under 10 Oe

Fig.30a Temperature dependence of magnetic susceptibility and magnetic hardness (reciprocal magnetic susceptibility) of $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ under 1000 Oe., green dotted line represents the fitting according to Curies-Weiss law.

Fig. $30 b x \bullet T$ as a function of temperature for $\mathrm{Fe} 3(B N A) 6 O$

Figure 30a is the temperature dependence of magnetic susceptibility and magnetic hardness (reciprocal magnetic susceptibility) of complex 2, green dotted line represents the fitting according to Curies-Weiss law. Figure $30 \mathrm{~b} x \mathrm{~T}$ as a function of temperature for complex 2.

From the temperature dependence of magnetic hardness $\chi-1$ we can observe that the measured sample have a paramagnetic behavior from room temperature to about 120K described by a Curie-Weis law:

$$
\chi=\frac{C}{T-\theta}
$$

where, $\theta=-175(\mathrm{~K})$, the Curie Constant C is:

$$
\mathrm{C}=\frac{\Delta T}{\Delta(1 / \chi)}=\frac{350+175}{13200} \approx 4 \times 10^{-2}
$$

In statistical theory of paramagnetism, Langevin states that the thermal variation of susceptibility is:

$$
\chi=\frac{M}{H}=\frac{N \mu_{e f f}^{2} \mu_{0}}{3 k_{B} T}=\frac{C}{T}
$$

Where N is the ion concentration, $\mu 0$ is the magnetic constant, kB is the Boltzmann constant. N can be estimated from the formula weight of $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$.

From this relation we know that the Curie Constant C is equal to $\chi \mathrm{T}$ and is proportional to the effective magnetic moment $\mu_{\text {eff }}$ and:

$$
\mu_{e f f}=\sqrt{\frac{3 k_{B} C}{\mu_{0} N}} \approx 5.6 \mu_{B}
$$

Where $\mu_{\mathrm{B}}$ is Bohr magneton. The result is close to the theoretic calculation of spin state of $\mathrm{Fe}^{+3}$ which is 5.92 , while is in the middle of $\mathrm{Fe}^{+2}$ (5.4) and $\mathrm{Fe}^{+3}$ (5.9) experimentally. See Table 6 below. ${ }^{33}$

Table 6. Effective magneton numbers for iron group ions

| Ion | Configuration | Basic level | $\begin{gathered} p(\text { calc })= \\ g[J(J+1)]^{1 / 2} \end{gathered}$ | $\begin{gathered} p(\text { calc })= \\ 2[S(S+1)]^{1 / 2} \end{gathered}$ | $p(\operatorname{cxp})^{\text {a }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Ti}^{3+}, \mathrm{V}^{4+}$ | $3 d^{1}$ | ${ }^{2} D_{3 / 2}$ | 1.55 | 1.73 | 1.8 |
| $\mathrm{V}^{3+}$ | $3 d^{2}$ | ${ }^{3} \mathrm{~F}_{9}$ | 1.63 | 2.83 | 2.8 |
| $\mathrm{Cr}^{3+}, \mathrm{V}^{2+}$ | $3 d^{3}$ | ${ }^{4} F_{3 / 2}$ | 0.77 | 3.87 | 3.8 |
| $\mathrm{Mn}^{3+}, \mathrm{Cr}^{2+}$ | $3 d^{4}$ | ${ }^{5} D_{0}$ | 0 | 4.90 | 4.9 |
| $\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}$ | $3 d^{5}$ | ${ }^{6} S_{5 / 2}$ | 5.92 | 5.92 | 5.9 |
| $\mathrm{Fe}^{2+}$ | $3 d^{6}$ | ${ }^{5} D_{4}$ | 6.70 | 4.90 | 5.4 |
| $\mathrm{Co}^{2+}$ | $3 d^{7}$ | ${ }^{4} F_{9 / 2}$ | 6.63 | 3.87 | 4.8 |
| $\mathrm{Ni}^{2+}$ | $3 d^{8}$ | ${ }^{3} F_{4}$ | 5.59 | 2.83 | 3.2 |
| $\mathrm{Cu}^{2+}$ | $3 d^{9}$ | ${ }^{2} D_{5 / 2}$ | 3.55 | 1.73 | 1.9 |

The calculation of the Curie Constant C and effective magnetic moment suggests a mixture of spin state of $5 / 2$ and 2 corresponding to Fe (III) and Fe (II) ions and also a
complex spin states due to the Fe ions. Applying a linear fit between 150 and 350 K , according to the Curie-Weiss law, a negative Curie-Weiss temperature of -175 K was obtained, indicating a predominant antiferromagnetic exchange interaction between spin carriers below -175 K . The regular decrease of the $\chi \mathrm{T}$ vs T plot from room temperature down to 120 K is a signature of paramagnetic order. A slope change at around 120 K may corresponds to the formation of weak short-range ferromagnetic order. More measurements on the electric and thermal properties are suggested to conduct to deeply understand the magnetic and electric structure of the sample.

Fig. 31 M-H loopos of $\mathrm{Fe} 3(\mathrm{BNA}) 6 \mathrm{O}$ at $10 \mathrm{~K}, 150 \mathrm{~K}$, and 375 K , under magnetic fields between $-7 T$ and $7 T$.

Figure 31 is Hysteresis loop, M-H curve of complex 2 at T equal to $10 \mathrm{~K}, 150 \mathrm{~K}$, 375K, under the external magnetic field ranges from -7T to 7T. As shown by Fig. 31, the M-H curve at 10 K showed "superparamagnetic" behavior, as it has a clear deviation from the linear relation (red dash line). The observed possible superparamagnetic
phenomenon at lower temperature indicates a competition between anisotropy energy, i.e. KV where K is the anisotropy constant and V is the volume, and thermal energy, i.e. kBT where kB is the Boltzmann constant and T is temperature of assemblies of small particles, which show magnetization behavior that is qualitatively similar to that of local moment paramagnetic materials, but with a much larger magnetic moment.

## CHAPTER V

## CONCLUSION

The focus of this thesis was to design and synthesize new coordination polymers using crystal engineering, hydrothermal synthesis, and self-assembly. After the single crystals were successfully obtained, a single crystal was selected for X-ray diffraction analysis. Once the crystal structure was solved successfully, the new coordination polymer were analyzed for their thermal properties using DT/TGA analyzer and FT-IR instrument. The composition of the polymer was analyzed using elemental analysis by Galbraith Laboratories. The magnetic properties were also analyzed using superconducting quantum interference device (SQUID). This thesis reports the design and synthesis of the new coordination polymer $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$. This coordination polymer has one chemical formula but two different structures.

The IR analysis confirmed the structure of the ligand exists in the coordination polymer structure. The element analysis confirmed the coordination polymer chemical formula.

The thermal analysis shows that the coordination polymer $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ was stable up to about $375^{\circ} \mathrm{C}$. The decomposition process of the polymer is the heat absorbing process. Compared to the copper coordination polymers, the $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ has higher stable temperature. This is likely because the coordination bonds in iron's polymer are stronger than the coordination bonds in the copper's polymer. Future research in the thermal analysis of coordination polymer should be comparing the polymer with same metal and different ligands, or same ligands and different metal.

The magnetic analysis shows the coordination polymer $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$ behaves like a typical paramagnet without obvious magnetic anomaly which is sensitive to small magnetic field such as the superconductivity or to say diamagnetism.

Hydrothermal synthesis has developed more than 10 years. With hydrothermal synthesis, many of the fascinating coordination polymers were synthesized. The coordination polymer reported in this thesis research is an example of using hydrothermal synthesis. It allowed the self-assembly process to take place inside the Teflon bomb. Crystal engineering is the basic step of the coordination polymer synthesis. The overall structure is depending on the choices of the metal and ligand. In this thesis research, iron was chosen as metal center. It provides the six coordinate octahedral structure. The ligand decided the polymer can be the shape of the coordination polymer. In $\mathrm{Fe}_{3}(\mathrm{BNA})_{6} \mathrm{O}$, the oxygen and nitrogen were connected to the iron atom. The rotation of along the C-O bond gives two different structure. One of them is a two-dimensional layer structure and the other one is three dimensional cubic structure. The coordination pattern is the same as the crystal engineering predicted.

Coordination chemistry has been developing for more than 20 years. The research of coordination polymer is getting more and more popular including the uses of coordination polymer including gas absorbing, semiconductors, heat resistant, and catalysts. By using the synthesis techniques of crystal engineering, hydrothermal synthesis, and self-assembly, more and more new coordination polymers can be synthesized.
